09/613,616

REMARKS

This is a full and timely response to the non-final Official Action mailed July 7, 2005. Reconsideration of the application in light of the above amendments and the following remarks is respectfully requested.

Substitute Specification:

A substitute specification is filed herewith to correct typographical errors and other informalities in the specification. No new matter has been added.

Status of Claims:

By the present paper, various claims are amended. Claims 2, 3, 10, 11, 14, 21, 22 and 25 have been cancelled. New claims 30-37 have been added. Thus, claims 1, 4-9, 12, 13, 15-20, 23, 24 and 26-37 are currently pending for further action.

Prior Art:

With regard to the prior art, the Office Action rejected claims 1, 2, 11-13, 22-26 and 29 as anticipated under 35 U.S.C. § 102(e) by U.S. Patent No. 6,122,759 to Ayanoglu et al. ("Ayanoglu"). For at least the following reasons, this rejection is respectfully traversed.

Claim 1 recites:

A wireless access point for use in a local area network for transmitting data among networked devices, *the wireless access point being incorporated into a first networked device* and comprising:

a wireless transceiver for wireless receiving and transmitting a data signal among said networked devices; and

40002-0007

09/613,616

a controller for controlling said transceiver to receive and transmit said data signal among networked devices within range of said transceiver so as to wirelessly relay said data signal among said networked devices in accordance with a designated recipient device of said data signal specified by said data signal;

wherein said controller both (1) transmits data originating on said first networked device in which said wireless access point is incorporated and (2) relays data in accordance with a designated recipient among any of the other said networked devices within range of said wireless access point.

(emphasis added).

In contrast, Ayanoglu does not teach or suggest a wireless access point that is incorporated into a networked device and “both (1) transmits data originating on said first networked device in which said wireless access point is incorporated and (2) relays data in accordance with a designated recipient among any of the other said networked devices within range of said wireless access point” as claimed. Support for this feature of the claims can be found in the Applicant’s originally filed specification at, for example, Fig. 2A and the accompanying text on page 8 and paragraph 0067 in the substitute specification.

“A claim is anticipated [under 35 U.S.C. § 102] only if each and every element as set forth in the claim is found, either expressly or inherently described, in a single prior art reference.” *Verdegaal Bros. v. Union Oil Co. of California*, 2 U.S.P.Q.2d 1051, 1053 (Fed. Cir. 1987) (emphasis added). See M.P.E.P. § 2131. For at least this reason, the rejection of claim 1 and its dependent claims should be reconsidered and withdrawn.

Independent claim 12 recites:

A method of extending a local area network with one or more wireless access points each comprising a wireless transceiver for wirelessly receiving and transmitting a data signal among networked devices, the method comprising:

connecting a said wireless access point to a power source;

40002-0007

09/613,616

controlling said transceiver to receive and transmit said data signal among networked devices within range of said transceiver so as to wirelessly relay said data signal among said networked devices in accordance with a designated recipient device of said data signal; and

providing an electrical outlet on said wireless access point such that another device can be connected to said power source through said wireless access point.

(emphasis added).

In contrast, Ayanoglu does not teach or suggest "providing an electrical outlet on said wireless access point such that another device can be connected to said power source through said wireless access point." Support for this feature of the claims can be found in the Applicant's originally filed specification at, for example, page 13, third and fourth full paragraphs (paragraphs 0066 and 0067 in the substitute specification), and Fig. 6B (element 691).

Again, "[a] claim is anticipated [under 35 U.S.C. § 102] only if each and every element as set forth in the claim is found, either expressly or inherently described, in a single prior art reference." *Verdegaal Bros. v. Union Oil Co. of California*, 2 U.S.P.Q.2d 1051, 1053 (Fed. Cir. 1987) (emphasis added). See M.P.E.P. § 2131. For at least this reason, the rejection of claim 12 and its dependent claims should be reconsidered and withdrawn.

Independent claim 23 recites:

A wireless access point for use in a local area network for transmitting data among networked devices, the wireless access point comprising:

transceiver means for wireless receiving and transmitting a data signal among said networked devices; and

controller means for controlling said transceiver means to receive and transmit said data signal among networked devices within range of said transceiver means so as to wirelessly relay said data signal among said networked devices in accordance with a designated recipient device of said data signal;

40002-0007

09/613,616

said wireless access point further comprising a weatherproof housing and electrical power connector for connection with a power supply for powering said wireless access point such that said wireless access point is configured to be deployed outside.

(emphasis added).

In contrast, Ayanoglu does not teach or suggest a "wireless access point further comprising a weatherproof housing and electrical power connector for connection with a power supply for powering said wireless access point such that said wireless access point is configured to be deployed outside." Support for this feature of the claims can be found in the Applicant's originally filed specification at, for example, page 13, fourth full paragraphs (paragraph 0067 in the substitute specification).

Again, "[a] claim is anticipated [under 35 U.S.C. § 102] only if each and every element as set forth in the claim is found, either expressly or inherently described, in a single prior art reference." *Verdegaal Bros. v. Union Oil Co. of California*, 2 U.S.P.Q.2d 1051, 1053 (Fed. Cir. 1987) (emphasis added). See M.P.E.P. § 2131. For at least this reason, the rejection of claim 23 and its dependent claims should be reconsidered and withdrawn.

Claim 24 recites:

A system including a wireless data local-area-network that supports wireless portable devices, the system comprising:
a plurality of wireless access points in said network which receive wireless transmissions from said portable devices;
a processor for determining a location of a portable device based on transmissions received by any of said plurality of access points from said portable device, wherein said processor may be in said wireless portable device or may be in an access point or other networked device;
wherein a functionality of said portable device is altered in response to said determined location.

(emphasis added).

40002-0007

09/613,616

Independent claim 29 similarly recites:

A method of controlling a wireless portable device which is part of a wireless data local-area-network that supports wireless portable devices, said network further comprising a plurality of wireless access points which receive wireless transmissions from said portable device, and a device, which is incorporated into said portable device or into said network, for determining a location of said portable device based on transmissions received by any of said plurality of access points from said portable device, *the method comprising altering a functionality of said portable device in response to said determined location.* (emphasis added).

In contrast, Ayanoglu fails to teach or suggest a system or method in which the "a functionality of said portable device is altered in response to said determined location" as claimed. In the regard, the Office Action refers to Ayanoglu at col. 9, lines 38-51. This portion of Ayanoglu describes determining the location of a portable device within the network, but does not teach or suggest that the functionality of the device is altered in response to its determined location as claimed. This subject matter is not taught or suggested by the prior art of record.

Again, "[a] claim is anticipated [under 35 U.S.C. § 102] only if each and every element as set forth in the claim is found, either expressly or inherently described, in a single prior art reference." *Verdegaal Bros. v. Union Oil Co. of California*, 2 U.S.P.Q.2d 1051, 1053 (Fed. Cir. 1987) (emphasis added). See M.P.E.P. § 2131. For at least this reason, the rejection of claims 24 and 29, and their respective dependent claims, should be reconsidered and withdrawn.

In addition to the principal § 102 rejection based on Ayanoglu, a number of § 103 rejections were made as to the dependent claims. Specifically, claims 3, 6, 7, 14, 17 and 18 were rejected under 35 U.S.C. § 103(a) over the combined teachings of Ayanoglu and Matsuo (of record). Claims 4 and 5 were rejected under 35 U.S.C. § 103(a) over the combined

40002-0007

09/613,616

teachings of Ayanoglu, Matsuo and Gilbert (of record). Claims 5 and 16 were rejected under 35 U.S.C. § 103(a) over the combined teachings of Ayanoglu, Matsuo and Beamish (of record). Claims 8, 9, 19 and 20 were rejected under 35 U.S.C. § 103(a) over the combined teachings of Ayanoglu, Matsuo and Durdik (of record). Claims 10 and 21 were rejected under 35 U.S.C. § 103(a) over the combined teachings of Ayanoglu and Zhong (of record). Claim 27 was rejected under 35 U.S.C. § 103(a) over the combined teachings of Ayanoglu and Kubler (of record). Claim 28 was rejected under 35 U.S.C. § 103(a) over the combined teachings of Ayanoglu and Portaro (of record).

These rejections are all respectfully traversed for at least the same reasons given above with respect to the particular independent claim from which each ultimately depends.

Reconsideration and withdrawal of these rejections is respectfully traversed.

40002-0007

09/613,616

Conclusion:

The newly added claims are thought to be patentable over the prior art of record for at least the same reasons given above with respect to the original independent claims.

Therefore, examination and allowance of the newly added claims is respectfully requested.

For the foregoing reasons, the present application is thought to be clearly in condition for allowance. Accordingly, favorable reconsideration of the application in light of these remarks is courteously solicited. If any fees are owed in connection with this paper which have not been elsewhere authorized, authorization is hereby given to charge those fees to Deposit Account 18-0013 in the name of Rader, Fishman & Grauer PLLC. If the Examiner has any comments or suggestions which could place this application in even better form, the Examiner is requested to telephone the undersigned attorney at the number listed below.

Respectfully submitted,

TITLE OF THE INVENTION

Wireless Extension of Local Area Networks

RELATED APPLICATIONS

[0001] This application is a continuation-in-part of U.S. Patent Application Nos. 09/525,340, filed March 14, 2000 and 60/158,725, filed October 11, 1999 (the "Parent Applications"). Both of which are incorporated herein by reference in their entireties.

FIELD OF THE INVENTION

[0002] The present ~~invention specification~~ relates to the field of wireless data networks. More specifically, the present ~~invention specification~~ relates to base units that can be used to extend wireless local area networks ("LAN's").

BACKGROUND OF THE INVENTION

[0003] Local Area Networks, or LAN's, are presently used to connect computers, printers, terminals, and other devices that benefit from interconnectivity within a facility, e.g. a home, office or business environment. LAN's are used to share information between users, to share devices such as printers, to enable point-of-sale transactions, and to share connectivity to the Internet.

[0004] LAN's are most commonly found in places of business, particularly office buildings. LAN's allow workers to communicate with each other, share files and information, and to share peripherals such as printers and scanners. LAN's are also common in the retail environment, enabling credit card processing and inventory tracking at the point-of-sale.

[0005] Traditional LAN's are implemented with a wired network protocol such as Ethernet or AppleTalk®. The wired network backbone is physically brought to, and a connection dropped at, each location that a worker or peripheral must access the network. Peripherals or computers then simply plug into the wired jacks that are installed in each such location.

[0006] As can be imagined, the installation of these wired networks to each jack can be time-consuming and expensive. And, once the wired network is installed,

40002-0007

09/613,616

reconfigurations to the work environment are equally difficult and further complicated by the presence of the existing wired network.

[0007] Because of the expense of installing and reconfiguring the wired network, wireless networks are increasing in popularity. In particular, wireless networking is one of the technologies that is increasing the popularity of in-home networks. Installing traditional wired networks in the home environment proves to be more expensive than in the office environment because walls and ceilings in a home are traditionally designed with less accessibility for wiring as compared with walls and ceilings in an office environment. Wireless networks overcome this obstacle by allowing networked computers to wirelessly communicate with each other, creating wireless networking within the home or office.

[0008] Fig. 1 shows a typical implementation of a wireless network with wireless access points (100, 102). The access points (100, 102) are wireless transceivers physically connected to the wired LAN. A device with wireless communication capability within the range of the access points (100, 102) can be included in the LAN by wirelessly communicating with the network through an access point (100, 102). Fig. 1 shows the conventional implementation of such a network which has networked devices both wired (110, 112, 120) and wirelessly (114, 130) connected to the wired network backbone (e.g., 140). This combination is for illustrative purposes and may vary significantly in practical implementation.

[0009] Fig. 1 depicts an example of a conventional wireless network in the computing environment. In the home or office environment, the devices on the network could easily and alternatively be entertainment equipment, such as stereos, televisions, VCR's, or speakers. Portable devices (130) could be cameras, phones, or internet appliances.

[0010] For example, in Fig. 1, two personal computers (110, 112) are networked together in a traditional wired network. A peripheral (120), such as a printer, is connected directly to the network, giving both personal computers (110, 112) equal visibility to the peripheral (120).

[0011] The center of the wired network backbone is the network hub (140). This hub manages all of the network traffic, coordinating messages between all of the devices

40002-0007

09/613,616

on the network. It is also responsible for managing each device's connection to the internet (160).

[0012] The access points (100, 102) are conventional wireless transceivers in that they connect through a wire directly to the network backbone and the network hub (140). The wireless coverage area of each device having wireless communications capability is defined by the circle around that device. Personal computer (114) is within range of access point (102), i.e., the access point (102) is within the transmission range of the computer (114) and vice versa. Communication through the access point (102) provides the computer (114) with network connectivity to the other personal computers (110, 112), to peripheral (120), and to the internet (160), through the network hub (140). The wireless communication circuitry built into personal computer (114) is not specifically illustrated and is essentially the same as the known circuitry in the access points (100, 102).

[0013] When application programs running on the personal computer (114) send messages to the other devices on the network or to the internet (160), those programs do not need knowledge of the wireless network. Application programs are those programs running under the operating system which provide features and services to the user. If the application programs are using an internet protocol such as TCP/IP running over the network, the same TCP/IP protocol can run over the wireless network. Low-level drivers in the personal computer (114) implement all network traffic over the wireless network, as opposed to low-level drivers in personal computers (110, 112) that implement all network traffic over the wired connections.

[0014] Portable device (130) establishes a similar connection to the network through access point (100) and network hub (140). The circle of wireless coverage around portable device (130) is smaller than the other coverage areas, indicating a lower-power wireless transmitter suitable for implementation in such a portable device (130). Implementation of the wireless circuitry in the portable device (130) is essentially the same as the circuitry found in the access points (100, 102) and other devices (e.g., 114), except for the smaller size and lower transmission power.

[0015] Application programs running on the portable device (130) also do not need to know about the wireless network if running an internet protocol such as TCP/IP. The portable device (130) simply needs drivers capable of interfacing to the wireless

40002-0007

09/613,616

network circuitry, e.g. access points (100, 102). If the wireless communication of portable device (130) was disabled and a wired connection was formed directly to network hub (140), the application programs would work the same.

[0016] During normal operation, portable device (130) may fall into an area that allows wireless communication with both access points (100, 102) at the same time. In this scenario, the networking software determines which access point to use, or whether both access points should be used, during wireless communication. It is also possible for portable device (130) to be within the range of wireless communication with three or more access points simultaneously.

[0017] Wireless networks such as that illustrated in Fig. 1 have the advantages of being easier to build and reconfigure. Once the wireless access points (100, 102) are installed and connected to the wired network (140), computers (114) and peripherals with wireless capability can be placed or moved anywhere in the coverage area of the access points (100, 102).

[0018] Small entirely wireless LAN's can also be built without the use of such access points if all the networked devices are kept within radio frequency ("RF") range of each other. However, this requires relatively powerful and expensive wireless transceivers in networked device or necessarily limits the size of the area over which the LAN is deployed. The wireless connection is typically a low power RF connection that only covers a 150-foot radius. Many wireless networks use RF in the ISM band, and many commercial wireless networks employ the IEEE802.11 or OpenAir protocols in the 2.4GHz band. There are many other protocols that are running over many other frequency bands, and many more on the way.

[0019] Thus, significant drawbacks to this wireless network implementation include the relatively high cost and size of the RF circuitry required to communicate from one side of a home to the other. This is not so significant problem for desktop computers or printers in which the necessary RF transceiver can be deployed with relative ease. However, it becomes an important issue with handheld Personal Digital Assistants (PDA's), cellular telephones, digital cameras, and other portable devices (130) that benefit from connection to the wireless network.

[0020] Therefore, in order to avoid severe limitations on the movement of portable devices within the LAN, additional access points must be added to insure

40002-0007

09/613,616

complete coverage of the desired area. The addition of each further access point requires wired connections to be added to furnish the communication link between that access point and the network. This obviously complicates the installation of the network.

[0021] Consequently, there is a need in the art for an implementation of an access point that extends the wireless coverage into areas that allow wireless communication with portable devices that otherwise would be out of range without requiring the addition of a wired connection to that access point.

SUMMARY OF THE INVENTION

[0022] ~~It is an object of the present invention to address the above-described needs and others. Specifically, it is a object of the~~The present invention specification describes to provide a means and method of extending a wireless LAN with great flexibility as to how and where additional coverage area is established. It is a further object of the present invention to provide~~For example, the indicated means and method of extending a wireless LAN described herein do which does not require additional wiring for further access points and is are therefore easy to reconfigure as dictated by the evolving needs of the network. It is also an object of the present invention~~The present specification also describes how to increase the connectivity between the LAN and portable devices such that communication is enabled between the LAN and portable devices that would otherwise be out of range of the in-home or in-office wireless network.

~~[0023] Additional objects, advantages and novel features of the invention will be set forth in the description which follows or may be learned by those skilled in the art through reading these materials or practicing the invention. The objects and advantages of the invention may be achieved through the means recited in the claims to follow.~~

~~[0024] To achieve these stated and other objects, the present invention may be embodied and described as a new type of wireless LAN access point that increases the coverage area of a wireless LAN without requiring the expense and effort of installing a wired network connection to the new access point.~~

[0023] The new access point replaces a portion of the traditional wired network with a wireless link to the next adjacent wireless device on the LAN. This device could be the desired computer or peripheral that a portable device wishes to communicate with,

40002-0007

09/613,616

or it could be a traditional access point with a wired connection to the desired device. Additionally, the next adjacent device could be another wireless access point that subsequently wirelessly communicates with the next wireless device adjacent to it.

[0024] The architecture of the access point and the implemented wireless LAN is the same as that disclosed in Parent Applications. This access point and wireless LAN architecture can be extended to networks outside places of business and into the home and office environments.

[0025] With wireless communication links between the wireless access points, the only physical connection needed is to provide power to the circuitry. This allows for very efficient physical designs for the home or office environment, where power can be received from a nearby AC outlet. The design can be implemented either with a box with a power cord coming from it, or with the wall plugs built in as part of the unit. Additionally, the circuitry could be implemented in any electronic device that already has power provided to it. This electronic device may optionally use the wireless circuitry to enhance its own functionality.

[0026] Once the connection to AC power is made through an outlet, an alternate design can be implemented where the wired network of the in-home or in-office LAN uses the AC electrical wires already installed. Computers and peripherals on the network would use existing modems that send and receive network information on the AC power lines. Transmission of the data is typically achieved by modulating a carrier that is much higher in frequency than the incoming AC power at 50 or 60 Hz. Using this scheme, access points would wirelessly connect with devices within RF range, and would tie these devices to the rest of the LAN through the AC power lines.

[0027] All of the described network scenarios and more can be more easily implemented if the wireless LAN was made up of small devices that simply plug into an outlet and provide wireless connectivity for the devices in that room. The box that plugs into the outlet may have some status indication, and possibly a power or a mode switch, as its entire external interface.

[0028] The present invention ~~also encompasses~~ specification also describes a system including a wireless data local-area-network that supports wireless portable devices where the system includes a number of wireless access points in the network that receive wireless transmissions from the portable devices; and a process for determining

40002-0007

09/613,616

the location of a portable device based on the transmissions received by any of the access points from said portable device. The location determination may be performed by either the portable device or the network. The functionality of the portable device can then be controlled in response to the determined location of the portable device. For example, a wireless phone may control its ringer volume or voice mail features based on its location, or a personal digital assistant may control the data provided and features available based on its location. This aspect of the invention may be implemented in a traditional LAN with wireless access points wired to the LAN or a completely wireless LAN as described herein.

BRIEF DESCRIPTION OF THE DRAWINGS

[0029] The accompanying drawings illustrate examples of the present invention and are a part of the specification. Together with the following description, the drawings demonstrate and explain the principles ~~of the present invention described herein.~~

[0030] Fig. 1 is a block diagram of a conventional wired LAN with conventional access points.

[0031] Fig. 2A is a block diagram of a completely wireless LAN with wireless access points ~~according to the present invention.~~

[0032] Fig. 2B is a block diagram of a conventional wireless LAN which has been extended using the completely wireless access points ~~according to the present invention.~~

[0033] Fig. 2C is a block diagram of a wireless LAN which has been extended using a plurality of communicating access points ~~according to the present invention.~~

[0034] Fig. 3 is a block diagram of a combination of a wired LAN over power lines and power-line access points ~~according to the present invention.~~

[0035] Fig. 4 is a block diagram of a wireless access point ~~according to the present invention.~~

[0036] Fig. 5 is a block diagram of a power-line access point ~~according to the present invention.~~

[0037] Fig. 6A illustrates a first possible physical implementation of either the wireless access point or the power-line access point ~~according to the present invention.~~

[0038] Fig. 6B illustrates a second possible physical implementation of either the wireless access point or the power-line access point ~~according to the present invention.~~

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

~~[0040] Using the drawings, the preferred embodiments of the present invention will now be explained.~~

[0040] Fig. 2A shows a fully wireless implementation of the same devices depicted in Fig. 1 according to ~~the present invention~~ principles described herein. In this configuration, personal computers (210, 212) wirelessly communicate directly with each other. Also, personal computer (210) wirelessly communicates with peripheral (220).

[0041] As Fig. 2A shows for this implementation, there is no direct wireless communication link between personal computer (212) and peripheral (220). In this instance, all messages from personal computer (212) addressed to peripheral (220) must be relayed through personal computer (210). This complicates network implementation software for the wireless devices on the network, but tremendously improves the coverage area and installation implementation of the wireless network.

[0042] This message repeating can be extended to multiple stages of message relaying in order to provide communication between any two networked devices. For example, if personal computer (210) is not within range of personal computer (212), a message could be transmitted from the computer (212) to the peripheral (220) as follows. The message transmitted by the computer (212) would be relayed by access point (200), access point (202), and personal computer (210) before receipt by the peripheral (220).

[0043] The network in Fig. 2A can also allow direct communication, i.e., without any message relay, between two networked devices which are within range of each other. For example, personal computers (210, 212) have the ability to wirelessly communicate with each other directly. Similarly, the peripheral (220) may be deployed within range to the personal computer (212) so that communication between the computer (212) and the peripheral (220) can occur directly without message relaying. This eliminates the scenario in which the personal computer (210) must repeat or relay messages passed between the personal computer (212) and the peripheral (220).

[0044] Fig. 2A also shows the implementation of completely wireless access points (200, 202). As shown in the Fig. 2A, access point (200) directly wirelessly

40002-0007

09/613,616

communicates with personal computer (212), and access point (202) directly wirelessly communicates with personal computer (210). The access points (200, 202) are not wired to a LAN as in the prior art illustrated in Fig. 1. Consequently, the access points (200, 202) can be easily and readily deployed as necessary to extend the network as desired.

[0045] As shown in Fig. 2B, ~~[[the]]a wireless access point[[s]] (200, 202) of the present invention~~ can also be added to a traditional wired network as depicted in Fig. 1 to extend the coverage of the network. As shown in Fig. 2B, the wireless access point (200) wirelessly connects a portable device (130) with the rest of the networked devices through access point (100) which is, in turn, wired into the wired network through the network hub (140).

[0046] Fig. 2C further illustrates the principle ~~of the present invention~~ in which multiple access points can relay messages between networked devices in order to extend the network as needed with great flexibility. As shown in Fig. 2C, the portable device (230) is beyond the coverage of the access point (200). However, an intervening access point (200A) is provided which can relay messages between the portable device (230) and the access point (200). Through access point (200A), the portable device can send messages to or receive messages from any of the other devices constituting the network.

[0047] The nature of the access points (200, 200A, 202), ~~according to the present invention~~ which are completely wireless and require no wired connections, allow the access points to be implemented in a wide variety of physical embodiments. Specifically, the wireless access point of the present invention described herein, that do not require a wired network connection, may be a small box with a power cord extending from it, a box with power outlet plugs extending directly from the box, a box with a threaded connector to be screwed into a light fixture in place of a standard light bulb or a similar implementation. These physical implementations allow simple installation and flexibility that cannot be achieved with access points that require wired network connections.

[0048] The connection to the internet (260) for the LAN ~~is preferably~~ may be through personal computer (212) as shown in Figs. 2A and 2C. For any of the devices on the LAN to access the internet (260), ~~[[all]]messages must be~~ are routed through personal computer (212), as well as any devices necessary to get the messages to and from personal computer (212). Alternatively, the connection to the Internet may also be through a network hub (140) as shown in Fig. 2B, with wireless message relaying being

40002-0007

09/613,616

implemented as required to establish a link between the hub (140) and the networked device that is utilizing the Internet.

[0049] The connection to the internet described herein is a wired connection which may be preferred for its bandwidth. However, ~~the present invention also encompasses embodiments in which the LAN has a wireless connection to the internet through, for example, a wireless telephone or similar infrastructure, may also be included under the principles described herein.~~

[0050] Fig. 3 shows an alternative implementation of an access point according to ~~the present invention~~ that connects into an existing wired network that uses power-line modems and an AC power line for connectivity. As shown in Fig. 3, personal computers (310, 312) and peripheral (320) are all networked using existing power-line networking technology in the form of power-line modems (344, 346, 348). All messages for any devices on the network (e.g., 320, 310, 312, 314 and 330) are broadcast on the power line ~~(300301)~~, and each power-line modem (e.g., 340, 342, 344, 346, 348) ignores all messages except the ones intended for its device or a device wireless communicating with an access point (300, 302) connected to that power-line modem (340, 342). The intended recipient device of a message is the messages are defined by the internet protocol, such as TCP/IP.

[0051] As in the previous figures, the portable device (330) and personal computer (314) wirelessly communicate with access points (300) and (302) respectively. The access points (300, 302) receive the wireless messages from the portable device (330) and personal computer (314) and broadcast them to the power-line network ~~(300301)~~ through power-line modems (342) and (340) respectively. Any messages that are intended for the portable device (330) are received by power-line modem (342) and broadcast by access point (300) to the portable device (330). Any messages intended for personal computer (314) are received by power-line modem (340) and broadcast by access point (302) to the personal computer (314).

[0052] As in the previous figures, internet connection for the LAN is done through a single internet connection point (360) through personal computer (312). In this network topology, all messages bound for the internet (360) are placed on the AC power line, received by power-line modem (348), and passed to the internet connection (360) by personal computer (312).

40002-0007

09/613,616

[0053] Actual product implementation may combine access point (300) with power-line modem (342) in a single package, keeping similar physical implementations to that of access points (200, 202).

[0054] Fig. 4 shows ~~a preferred~~ an exemplary architecture of the wireless access points (200, 202) ~~according to the present invention~~. Controller (401) controls the state of the access point and the messages that are passed. For each message that is received, controller (401) determines if that message should be relayed to the next wireless device or ignored. Memory (405) is a combination of volatile and nonvolatile storage that holds the executable networking program running on the controller (401), configuration information, and temporary data. The wireless interface (420) is used to send and receive wireless messages to/from any other wireless devices within range, whether it is a portable device, the next relay point, or the final destination of the message.

[0055] Power is provided to the access point through connector (415). In some implementations, AC power will be supplied on connector (415), and an AC/DC power converter is incorporated within the access point. In other implementations, a regulated DC voltage comes in on connector (415), which eliminates the need for internal power conversion. The AC power supplied to the connector (415) may be from a conventional wall outlet into which the access point (200, 202) is plugged or a light bulb socket into which the access point (200, 202) is screwed.

[0056] An optional alternate power source (410) can be used to power the access point (200, 202) when external power is not present. The alternate power source (410) can be a rechargeable temporary storage, or can be a generating device that uses solar, wind, or water energy to generate power for the access point (200, 202). The alternate power source may be any combination of those described. In the case of a rechargeable storage device, charger (411) recharges the device when external power is present on connector (415).

[0057] Initial configuration and advanced diagnostics can be done using a test port (402). In-system diagnostics can be done through wireless commands received over the network, with results transmitted wirelessly back to the requestor.

[0058] Fig. 5 is a block diagram of a power-line network access point (e.g., 300, 302 in Fig. 3), implemented as the combination of access point (300, Fig. 3) and power-line modem (342, Fig. 3). Most blocks have the same functionality as in Fig. 4, with the

40002-0007

09/613,616

addition of the power-line modem (530). This modem (530) sends and receives messages between the controller (401) and the AC power line (~~300~~301, Fig. 3) through connector (415).

[0059] Fig. 6A shows a possible physical implementation of access points (200, 202, 300, 302). The housing (600) of the access point contains all of the circuitry included in Figs. 4 and 5, including any AC/DC power conversion device. Power is input through plug prongs (610), which plug directly into a wall outlet. To accommodate the different plug interfaces in different countries, the configuration of the prongs (610) may be interchangeable or there may be different versions of the physical implementation for different countries. To facilitate portability, the prongs (610) may fold away or collapse when not in use.

[0060] Status indicators (620) can be implemented using simple LED's. These indicators tell at a glance if the access point (200, 202, 300, 302) is powered on, transmitting wireless data, communicating with wireless devices, or is communicating with the LAN backbone. Other indicators that are deemed beneficial can be added or put in place of any of these functions.

[0061] The physical implementation of the access point may include a switch (630) for turning the device on or off. This would allow leaving the access point 'mounted' in the wall outlet while powering down the wireless network for any reason.

[0062] Fig. 6B illustrates an alternative physical implementation for the access point of the present invention. The embodiment of Fig. 6B is substantially identical to that of Fig. 6A, however, the prongs (610) are replaced by a threaded connector (690) which is sized to be screwed into a light socket that accepts a light bulb. The access point then draws power from the light socket.

[0063] A[[n]] second light bulb socket (691) may be provided in the housing of the access point and electrically connected to the socket in which the access point is disposed. In this way, a light bulb can be screwed into the access point socket (691) so that the access point draws power from the original bulb socket without preventing a light bulb from being powered by the socket as well.

[0064] Figs. 6A and 6B shows two possible physical embodiments for the access points of the present invention ~~described herein~~. Alternatively, the access point could be built into another fixed electronic device, such as a personal computer, television, or into

40002-0007

09/613,616

an outlet strip that already has a built-in surge protector. The access point could also be designed for implementation outdoors, which would entail the housing and the electrical connection being weatherproof.

[0065] The present ~~invention specification~~ also includes describes the method of extending the wireless coverage of a LAN with access points that do not require a wired network connection back to the LAN. The ~~invention includes specification also covers~~ the method of making a network of wireless access points that are easy to install, configure and reconfigure due to the wireless interface to the rest of the network.

[0066] Under the principles of the ~~present invention described herein~~, the wireless network can also be used to determine the location of a portable device connected wirelessly to the network and use that location in controlling the activity of the portable device. As detailed in the Parent Applications, the location of a portable device within the wireless LAN can be determined by the access point(s) that are within wireless communication range, i.e., communicating with the portable device. If an access point is communication with the portable device, for example, the known location of that access point is a reasonable proxy of the location of the portable device itself.

[0067] If necessary, finer location accuracy is possible by using a combination of two or more access points receiving transmissions from the portable device and measuring the relative signal strength received by each such access point. This can be done by the controller and hardware of the access point (200, 202). From this data, the approximate location of the portable device between the communicating access points within the wireless LAN coverage area can be determined in a manner that will be clear to those skilled in the art. This determination is made by the controller(s) of the access points (200, 202) communicating with the portable device (130). The determined location can then be communicated to the portable device (130). This principle can be applied to the home or office environment, with the network being aware of the particular room or office that a portable device is located within.

[0068] Alternatively, the portable device (130) can perform the same location determination based on the signals received from the access points (200, 202) with which it, the portable device (130), communicates. The controller and hardware of the portable device (130) are used to determine the location of the portable device (130) in the same

40002-0007

09/613,616

manner described above. The location of the portable device (130) may then be transmitted to the network as needed.

[0069] Features or information provided by the network to the portable device may differ based upon the location of a portable device within the wireless LAN coverage area. Several examples of this principle follow. In the home environment, a portable device may allow remote control functionality of the living room television when located within the living room. The same portable device may act as a recipe database when located in the kitchen. This may include having access to recipe information from a larger database on the network.

[0070] In the office environment, a personal digital assistant ("PDA") may be a portable networked device. Traditionally, PDA's are able to remind the holder of meeting and appointments. ~~Under the present invention,~~ ^{The location-based} functionality may display a map or other indication of the location of the meeting and provide direction to the meeting location from the present location of the portable networked device as determined by the network or the portable device. The device may also alert a user of an upcoming meeting earlier if the distance to the meeting is relatively far from the portable device's current location. A wireless phone may also be a networked device ~~under the principles of the present invention.~~ The networked phone may automatically raise the volume of its ringer if the network determines that the phone is located on a noisy factory floor or automatically lower the ringer volume if the network determines that the phone is located in a conference room or similar area. The networked phone may also automatically deactivate the ringer and take a message if an incoming personal call is received while the employee is sitting in, for example, his or her boss's office or a meeting for which "privacy" has been indicated.

[0071] Additionally, a wireless access point, being mounted in a fixed location within the LAN, may store information pertaining to that location to improve the functionality of the wireless network. For example, an access point located in the vendor conference room of an office may limit transactions and implement a tighter security level. An access point within the office of an employee may retrieve and store email messages for that employee, making email retrieval from a portable device instantaneous. The preferences of the access point can be set in a configuration mode or can be learned

40002-0007

09/613,616

by the network transactions that take place using the access point. These preferences can change if the location of a particular access point changes.

[0072] The preceding description has been presented only to illustrate and describe the invention. It is not intended to be exhaustive or to limit the invention to any precise form disclosed. Many modifications and variations are possible in light of the above teaching.

[0073] ~~The preferred embodiment was chosen and described in order to best explain the principles of the invention and its practical application.~~ The preceding description is intended to enable others skilled in the art to best utilize the invention in various embodiments and with various modifications as are suited to the particular use contemplated. It is intended that the scope of the invention be defined by the following claims.
